Travel Model Validation

HOUSTON-GALVESTON AREA COUNCIL

REGIONAL TRAVEL MODELS

2005 Cube Voyager Model Validation and Documentation Report

December 2009

1.0 Introduction

The Houston-Galveston Regional Travel Models are cooperatively developed and maintained by the Houston-Galveston Area Council (H-GAC), the Texas Department of Transportation (TxDOT) and the Metropolitan Transit Authority (METRO). This report documents the validation of the Houston-Galveston Regional "Track-1" Cube Voyerger Travel Models from the previous base year 2002 to 2005 base year.

A few years ago, the H-GAC's Emme/2 Track-1 2002 base year model was convereted and validated in the Cube Voyager environment. The Emme/2 Track-1 model is as result of enhancements and updates made to H-GAC's previous Travel Models known as the "Track-0" model set.

This report does not fully document the various model set components of this newly validated model, instead, documents those components that were addressed as part of the 2005 validation.

The development of the "Track-0" model set is documented in the following reports.

- *Development, Update and Calibration of 1985 Travel Models for the Houston Galveston Region, H-GAC, June 1991*
- *Estimation, Calibration, and Validation of the Houston Mode Choice Model - Technical Report*
- 1990 Houston Long-Range Patronage Forecasting Model Validation-Draft Technical Memorandum: Model Validation Methodology and Results
- *IH-10 Katy Freeway Major Investment Study: Service and Travel Forecasting Methodology, Version 3.0*

The 'Track-1" Travel Models represent an update of the "Track-0" models using updated (relative to the original 1984 survey) household and work-place survey data. In terms of model structure, the only significant change to the model set was the re-definition of trip purposes. The regional mode choice model is a nested logit model originally developed for incorporation into METRO's 1985 Houston Long-Range Patronage Forecasting Model based on 1985 travel survey information. The model was later enhanced for use in a Major Investment Study. The model has been re-calibrated to the year 2002 as part of the development of the Track-1 model set.

More information about the development and validation of the 'Track-1" Travel Models is documented from another report, titled "H-GAC Travel Model 2002 Validation Report".

1.1 Report Structure

Chapter 2 of the report discusses the development of land use, demographic and cost data for the 2005 Base Year. Included in this section is also a discussion and depiction of the zone system used in the H-GAC modeling efforts. Chapter 3 outlines the development of both highway and transit networks. This is followed in Chapter 4 with a discussion of travel forecasting procedures employed in the 1995 validation. The 2005 highway assignment

validation results are also summarized in Chapter 4. Chapter 5 discusses the development of an HPMS adjustment factor used in applications of travel model forecasts for air quality conformity and SIP development.

2.0 Land Use, Demographic & Cost Data Development

The eight-county Houston-Galveston-Brazoria Consolidated Metropolitan Statistical Area (CMSA) has been federally designated as the Transportation Management Area (TMA) for the Houston-Galveston region. The Houston-Galveston TMA extends over an area of 7,809 square miles. Land Use and Demographic forecasts for the TMA are developed by H-GAC.

2.1 Zone System Definition

Under 1990 (census related) geography, H-GAC has designated 3,000 detailed traffic analysis zones (TAZs) in the Houston-Galveston TMA. This includes 2,954 internal zones and 46 external stations. The internal zones are entirely within the TMA and the external stations are used to capture external-external and external-local trips into and through the TMA. The 2005 validation of the Cube models uses the same 3000 TAZ structure.

2.2 Base Year Demographic Estimates

Estimated Year 2005 households and Year 2005 employment were used as the primary demographic inputs for the Year 2005 validation of the travel models. Estimates of 2005 household were derived through interpolation of year 2000 TAZ-level estimates and forecasted year 2007 TAZ-level data. Definitional changes to employment categories instituted as part of a new demographic forecast resulted in a situation in which future year forecasts of employment that will be used in conjunction with this model set would be different than those of the Year 2005 employment data set. For this reason, employment estimates for the year 2005, which have consistent definitions to the future year employment were used in the validation of the 2005 Cube models. While use of the year 2005 employment results in an over-estimation of trip attractions, the H-GAC trip generation model scales attractions to match productions. Therefore, the total regional trip ends are the same as they would be if actual year 2005 employment was used.

2.3 Comparison of 1995 and 2005 Population/Household and 2005 Employment Estimates by County

Table 2.1 summarizes the household changes between 1995 and 2005. Regionwide households increased over 25 percent, from 1.488 million in 1995 to 1.865 million in 2005. Household growth by county ranged from a low of 18.5 percent in Galveston county to a high of more than 63 percent in both Montgomery county and Fort Bend county. Table 2.2 summarizes the household population growths by county from 1995 to 2005 (which excludes group quarters such as prisons).

Table 2.1
County Households for 2005 and 1995

County	1995	2005	Change from 1995	% Change
Harris	1,120,750	1,337,794	217,044	19.4%
Brazoria	68,337	95,757	27,420	40.1%
Fort Bend	87,477	142,821	55,344	63.3%
Waller	9,027	12,615	3,588	39.7%
Montgomery	81,556	133,227	51,671	63.4%
Liberty	21,760	26,577	4,817	22.1%
Chambers	7,710	10,779	3,069	39.8%
Galveston	89,143	105,619	16,476	18.5%
Total	1,487,755	1,865,189	379,429	25.5%

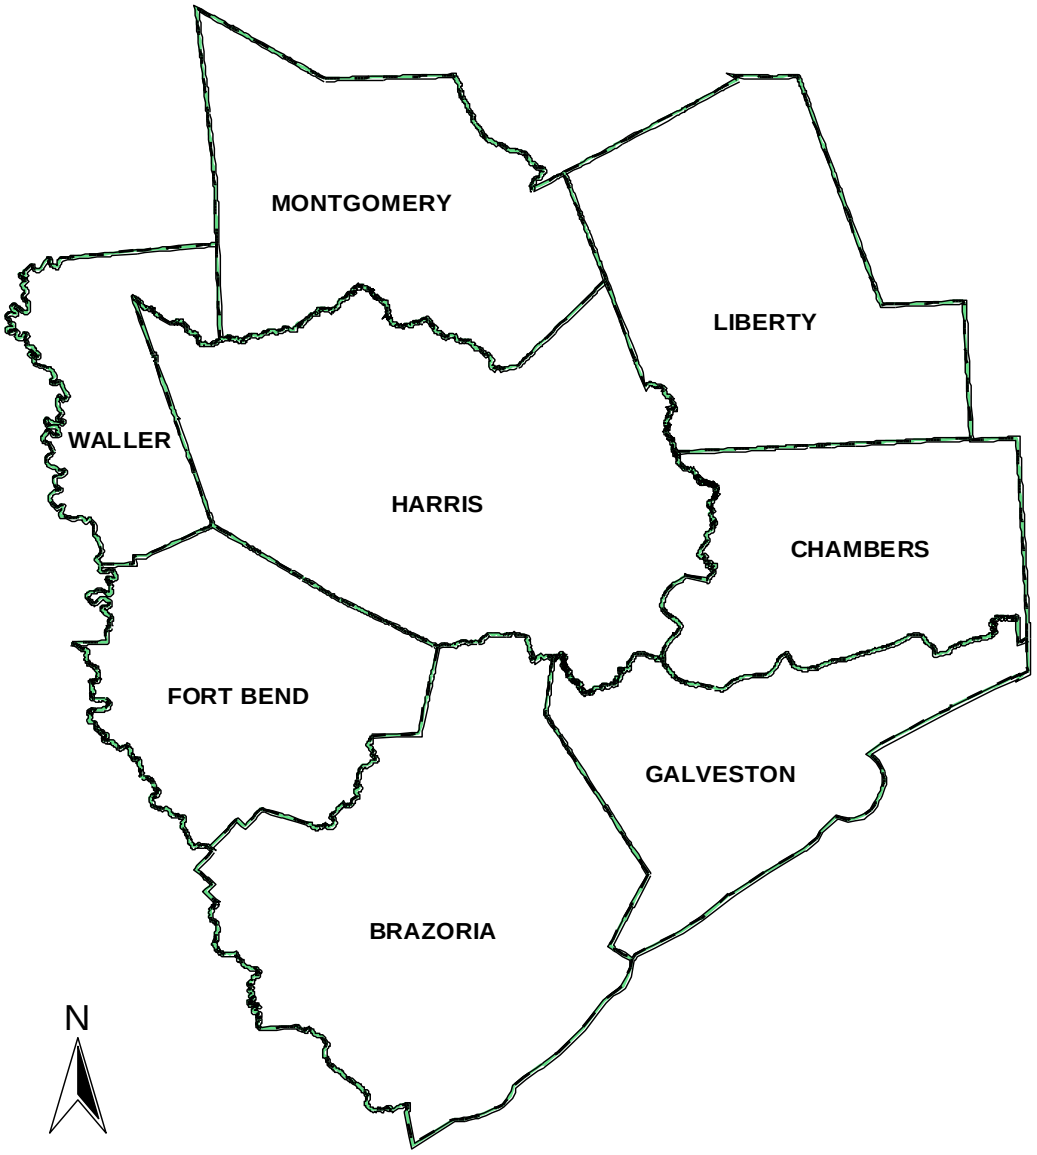
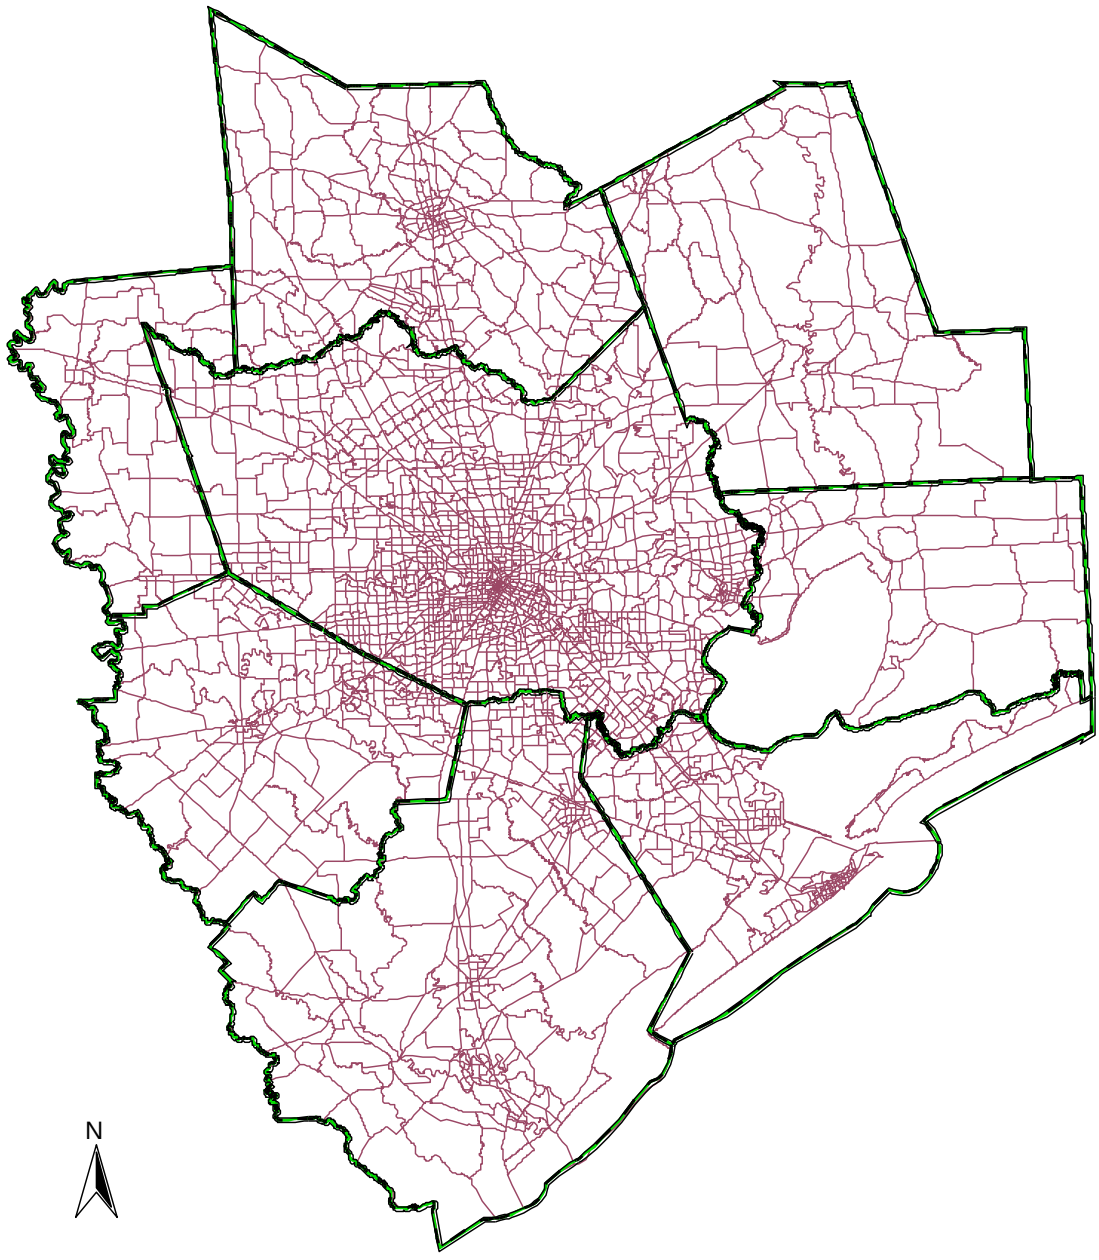
Figure 2.1 shows the eight counties in the Houston TMA. Figure 2.2 shows a map of H-GAC 3000 zone structure.

Figure 2.1
Houston-Galveston-Brazoria Consolidated Metropolitan Statistical Area (Eight Counties)



Source: H-GAC

Figure 2.2
H-GAC Zone Structure



Source: H-GAC

Employment for the eight county region increased comparably with population growth, 25.2 percent overall (Table 2.3). Harris County gained over 370,000 additional jobs (a 22 percent increase), while Fort Bend County employment grew by over 61,000 jobs, or 84 percent.

Table 2.3
County Employment for 1995 and 2005

County	1995 Employment	2005 Employment	Percent Change
Brazoria	74,327	92,284	24.2%
Chambers	7,505	7,982	6.4%
Fort Bend	72,804	133,919	83.9%
Galveston	92,566	105,884	14.4%
Harris	1,687,630	2,060,243	22.1%
Liberty	15,744	21,100	34.0%
Montgomery	70,276	107,814	53.4%
Waller	9,577	12,994	35.7%
Total	**2,030,429**	**2,542,220**	**25.2%**

2.4 Growth in Activity Centers Between 1995 and 2005

Table 2.4 summarizes the employment growth for the four major activity centers in Houston from 1995 to 2005. The Texas Medical Center experienced 23% increase in employment during that time, while the already well developed Houston CBD showed only a minor increase in employment in the same time period. The Galleria and Greenway Plaza areas experienced moderate increases of approximately 5% in employment between 1995 and 2005.

Table 2.4
Employment Change in Major Activity Centers for 1995 and 2005

Major Activity Center	1995 Employment	2005 Employment	Percent Change
CBD	135,223	137,461	1.7%
Texas Medical Center	75,223	92,476	22.9%
Greenway Plaza	52,242	55,035	5.3%
Uptown/Galleria	136,540	143,104	4.8%

Source: *H-GAC Trip Generation Input data for 1995 & 2005*

2.5 Cost Data

2.5.1 Auto Operating Costs

Auto operating cost is an input to the mode choice model and is used by the model in establishing the costs for the auto-related choice paths available in the roadway network. This cost reflects costs that are assumed be variable costs including gas, oil, tires and maintenance. As part of the 2005 validation, auto operating costs were updated to a year 2005 value. Then, using the Bureau of Labor Statistics (BLS) National CPI data, auto operating cost in 2005 dollars were then deflated to 1985 dollars to be consistent with the manner in which the mode choice model was calibrated. The auto operating cost for the year 2005 in 1985 dollars is 8.39 cents.

2.5.2 Toll Costs

Toll costs are used in the mode choice model in the development of costs paths for the auto-related modal choices of the mode choice model. For toll facilities that existed in the Year 2005, the toll costs are assigned to the links in the network that represent the locations where the tolls are actually collected. Table 2.5 lists the Year 2005 toll costs in 1985 dollars.

2.5.3 Transit Fares

The year 2005 transit fares were used as transit fare inputs to the 2005 validation of the Cube models. Table 2.6 presents the year 2005 transit fares, by service type, in 2005 dollars.

Table 2.6
Year 2005 Transit Fares
in 2005 Dollars

Local Bus	1.0
Light Rail	1.0
Express Bus	1.5
Commuter Bus	
0-10 miles	1.5
11-15 miles	2.5
16-20 miles	3.0
>20 miles	3.5

2.5.4 Parking Costs

Parking costs have been shown to have a significant effect on transit ridership levels and must be treated carefully. This variable is defined as an estimate of the actual (or average) out-of-pocket cost paid on a daily basis per vehicle. Table 2.7 summarizes the estimated parking costs used at the four major activity centers, including the Houston CBD, Greenway Plaza, Texas Medical Center, and Uptown/Galleria.

Table 2.7
Parking Costs for Activity Centers

Activity Center	Range of Costs	Average Cost
Houston CBD	$0.29-$6.73	$2.21
Greenway Plaza	$0.03-$1.30	$0.64
Texas Medical Center	$1.09-$2.06	$1.65
Uptown/Galleria	$0.07-$0.17	$0.10

3.0 Data Preparation and Transportation Network Development

Calibration and validation of the regional model was dependent upon observed travel behavior 1994 household, work place, commercial vehicle and external station travel surveys as well as a 1995 On-Board Transit Survey.

3.1 1994/1995 Travel Surveys

In 1994, H-GAC conducted a household travel survey for the Houston Metropolitan Area. The survey obtained general household and person data as well as specific activity-based trip information. Complete survey responses were obtained from 2,394 households, which generated in excess of 23,000 individual trip records.

The workplace travel survey involved the collection of travel data from employees and non-employees at 332 workplaces in the H-GAC region. Travel data was collected for over 5,000 employees and nearly 9,000 non-employees.

Surveying of external travel was performed at 24 of the 77 roadway crossings of the H-GAC region. The locations among the 77 were randomly selected and interviewed to determine vehicle destination.

3.2 Estimation of Highway Supply Characteristics

Highway supply characteristics that are required by the travel forecasting procedures include estimation of the highway level of service (LOS)(i.e., travel speed or time), parking costs, transit fares, terminal times, and auto operating costs.

The 2005 base year highway network includes key operational features for approximately 23,151 lane miles of roadways in the Houston-Galveston TMA, and consists of 28,888 nondirectional roadway links (excluding centroid connectors). Each link's physical and operating characteristics are described in a link data record. The Base Year 2005 network was constructed from the model calibration year 2002 network based on completed project information and input from local transportation agencies. Access to the highway network is provided by connecting links referred to as centroid connectors, which link internal TAZ centroids to nodes (points) in the highway network. These centroid connectors represent access to collectors, arterials, and other roadway facilities via local streets. The physical and operational characteristics represented with centroid connectors reflect zone size, proximity to the regional highway network, and the travel characteristics of local roadway facilities, which have the function of providing access to land uses within zones.

Data on physical attributes of the network, including roadway length, number of lanes, and median access type (divided or undivided) as well as operational characteristics such as average weekday traffic count and direction (one-way/two-way) were taken from the Roadway

Inventory. Link data items such as facility type classification, 24-hour speed, and 24-hour capacity are derived either from the above information or from a vehicle trip assignment. Highway link facility types include 42 different classifications. These are listed in Table 3.1 along with the link type codes for transit and HOV access.

Table 3.1
Link Type Classification Codes

Code	Description
0	Centroid Connector
1	Radial freeways without frontage roads
2	Radial freeways with frontage roads
3	Circumferential freeways without frontage roads
4	Circumferential freeways with frontage roads
5	Radial tollways without frontage roads
6	Radial tollways with frontage roads
7	Circumferential tollways without frontage roads
8	Circumferential tollways with frontage roads
9	Principal arterials with some grade separations
10	Principal arterials – divided
11	Principal arterials – undivided
12	Other arterials – divided
13	Other arterials – undivided
14	One-way pairs
15	One-way facilities
16	Major Collectors
17	Minor Collectors
18	Ferries
19	Saturated arterials
20	HOV/transitways (barrier-separated)
21	HOV ramps – bus only
22	Transfers from park-and-ride (PNR) to transit stop
23	Transfers from local bus to commuter/express bus
24	Transfers from walk access node to transit stop
25	Drive-access connectors
26	Bus only: from street to transit center (TC)
27	HOV-only slip ramps
28	Transfer from pseudo-PNR to transit stop
29	HOV terminal ramps
30	Rail
40	High-Occupancy Toll (HOT) Lane
41	HOT ramp to PNR/TC
47	HOT slip ramp
49	HOT ramp
50	Freeway frontage road
51	Tollway frontage road
52	Freeway/tollway ramps to/from frontage roads
53	Freeway/tollway direct connector (DC) ramps
60	Diamond lane (non-barrier separated HOV lane)

3.2.1 Link Capacity

Capacity and speed are the two most critical inputs into the highway network. Capacity values accorded to all roadway links represent Level of Service (LOS) E or maximum capacity based on the Highway Capacity Manual.

The following formula provided the basis for calculation of 24-hour link capacities:

$$C_{24} = \frac{(PHPD + PHNP)}{K}$$

Where: C_{24} = average daily traffic, or 24-hour capacity;
PHPD = capacity in the peak direction during the peak hour;
PHNP = capacity in the non-peak direction during the peak hour;
K = design hourly volume as a percent of ADT.

The peak hour / peak direction and peak hour / non-peak direction capacities are then calculated as a function of the hourly saturation flow rate:

$$PHPD = \frac{CS \times \frac{G}{C} \times \frac{V}{C} \times PHF \times U \times \frac{L}{2}}{1 + (P_t (E_t - 1))} + LTVP$$

Where: CS = saturation flow rate (2,150 vehicles/hour/lane for freeways, 1,800 for arterials);
G/C = percent of green time at signalized intersections (100 percent for freeways);
V/C = ratio of volume in the peak 15 minutes to capacity;
PHF = peak hour factor (V (volume) in highest hour / 4 × V in the peak 15 minutes);
U = lane utilization factor;
L = number of lanes;
P_t = percent of trucks;
E_t = truck equivalency factor; and
LTVP = left turn volume in the peak hour and peak direction.

Application of peak hour directionality factors to estimates of peak hour / peak direction volumes provides peak hour / non-peak directional volumes:

$$PHNP = PHPD \times \frac{1 - D}{D}$$

Where: D = percent of peak hour traffic in the peak direction.

3.2.2 Link Speeds & Automobile Travel Times

Link speed is used in trip distribution and as the input speed for the initial iteration in traffic assignment. The values of these link characteristics were carefully developed and closely

reviewed during the speed model calibration process. Two speed values are developed for all roadway links: a 24-hour speed and a peak hour speed.

The 24-hour link speed reflects an average daily speed for a given roadway facility type within a given area. Reasonable speed values were determined by testing values through comparisons to travel time contours developed from observed travel times speeds.

After link speeds and capacities have been developed, they are compiled into a look-up table used for all roadway facility types except HOV / transitways. The look-up table (Table 3.2) provides classifications of speed and capacity by facility type and number of lanes. The table is not used for centroid connectors.

Table 3.2
Speed and Capacity Look-Up Table

		Area Type 1		Area Type 2		Area Type 3		Area Type 4		Area Type 5

Time-of-day highway speeds that are used to develop automobile travel times are based on procedures adapted from the *Highway Capacity Manual* (HCM) methodology. These procedures differ somewhat between how freeway and non-freeway link speeds are estimated. Congested freeway speed is a function of free-flow speed (a function of speed limit and area type), speed at capacity (LOS E), and the volume-to-capacity (v/c) ratio for v/c ratios up to 1.0. For v/c ratios greater than 1.0, which represents saturated (LOS F) conditions, speed is estimated using a variant of the BPR function, with a multiplicative factor of 0.15 and v/c raised to the fourth power.

Procedures outlined in the HCM are used to estimate congested speeds on arterial or collector links. Congested arterial/collector link speed is a function of free-flow speed (a function of speed limit and area type), average intersection delay, signal spacing (segment), and the ratio of segment running time per mile to free-flow-speed running time per mile, where v/c ratios are 1.0 or less. For saturated (LOS F) conditions with v/c ratios greater than 1.0, speed is estimated

using a variant of the BPR function, with a multiplicative factor of 0.15 and v/c raised to the second power.

Peak period speeds are derived from a peak period equilibrium assignment. Since capacities used during the equilibrium assignment represent LOS E, the resulting link's V/C ratio can then be applied to the speed model to develop a peak hour speed. In other words, the traffic assignment results are post-processed to compute a reliable speed based on the assigned V/C ratio.

3.2.3 Auto Network Centroid Connectors

Speeds on centroid connectors are derived as a function of link length and zonal area type to reflect diversity in zone size, network density, and local street operational speeds. As an example, centroid connectors of less than one-tenth mile within the Houston CBD are assigned a speed of eleven miles per hour, which is considered the lowest practical facility speed that would not unduly penalize travel in that area.

CBD centroid connector speed is increased based on link length (for links less than one-tenth mile) as follows:

Travel Time (minutes) = (6.0 * link distance)
Travel Speed = 60 / (Travel Time / link distance)

For CBD centroid connectors longer than 0.10 miles, the speed is calculated as follows:

Travel Time (minutes) = (0.6 + 4 * (link distance - 0.1))
Travel Speed = 60 / (Travel Time / link distance)

As the area changes from CBD to urban to suburban, etc., centroid connector speeds increase more rapidly with increasing distance. This is based on the premise that as area type changes from denser areas (CBD) to less dense areas (suburban) zone sizes will increase accordingly. Thus, each of the other four area types have a unique set of equations for determining centroid connector speeds:

<u>Area Type 2 - Urban</u>

when link distance = 0.10 miles or less:
Travel Time (minutes) = (4.0 * link distance)
Travel Speed = 60 / (Travel Time / link distance)

when link distance > 0.10 miles and <= 0.25 miles:
Travel Time (minutes) = (0.4 + 3 * (link distance - 0.1))
Travel Speed = 60 / (Travel Time / link distance)

when link distance > 0.25 miles:
Travel Time (minutes) = (0.85 + 2.4 * (link distance - 0.25))
Travel Speed = 60 / (Travel Time / link distance)

Area Type 3 - Suburban

when link distance = 0.10 miles or less:
Travel Time (minutes) = (4.0 * link distance)
Travel Speed = 60 / (Travel Time / link distance)

when link distance > 0.10 miles and <= 0.25 miles:
Travel Time (minutes) = (0.4 + 3 * (link distance - 0.1))
Travel Speed = 60 / (Travel Time / link distance)

when link distance > 0.25 miles and <= 0.50 miles:
Travel Time (minutes) = (0.85 + 2.4 * (link distance - 0.25))
Travel Speed = 60 / (Travel Time / link distance)

when link distance > 0.50 miles:
Travel Time (minutes) = (1.45 + 2.0 * (link distance - 0.5))
Travel Speed = 60 / (Travel Time / link distance)

Area Type 4 - Fringe Suburban

when link distance = 0.10 miles or less:
Travel Time (minutes) = (3.5 * link distance)
Travel Speed = 60 / (Travel Time / link distance)

when link distance > 0.10 miles and <= 0.25 miles:
Travel Time (minutes) = (0.35 + 2.7 * (link distance - 0.1))
Travel Speed = 60 / (Travel Time / link distance)

when link distance > 0.25 miles and <= 0.50 miles:
Travel Time (minutes) = (0.755 + 2.2 * (link distance - 0.25))
Travel Speed = 60 / (Travel Time / link distance)

when link distance > 0.50 miles and <= 0.75 miles:
Travel Time (minutes) = (1.305 + 1.8570 * (link distance - 0.5))
Travel Speed = 60 / (Travel Time / link distance)

when link distance > 0.75 miles:
Travel Time (minutes) = (1.76925 + 1.714 * (link distance - 0.75))
Travel Speed = 60 / (Travel Time / link distance)

Area Type 5 - Rural

when link distance = 0.10 miles or less:
Travel Time (minutes) = (3.0 * link distance)
Travel Speed = 60 / (Travel Time / link distance)

when link distance > 0.10 miles and <= 0.25 miles:
Travel Time (minutes) = (0.30 + 2.4 * (link distance - 0.1))
Travel Speed = 60 / (Travel Time / link distance)

when link distance > 0.25 miles and <= 0.50 miles:
Travel Time (minutes) = (0.66 + 2.0 * (link distance - 0.25))
Travel Speed = 60 / (Travel Time / link distance)

when link distance > 0.50 miles and <= 0.75 miles:
Travel Time (minutes) = (0.96 + 1.714 * (link distance - 0.5))
Travel Speed = 60 / (Travel Time / link distance)

when link distance > 0.75 miles and <= 1.0 mile:
Travel Time (minutes) = (1.3885 + 1.5 * (link distance - 0.75))
Travel Speed = 60 / (Travel Time / link distance)

when link distance > 1.0 mile and <= 1.5 miles:
Travel Time (minutes) = (1.7035 + 1.333 * (link distance - 1.0))
Travel Speed = 60 / (Travel Time / link distance)

For rural zones exceeding 1.5 miles, link speeds are calculated as follows:

Travel Time (minutes) = (2.37 + 1.2* (link distance - 1.5))
Travel Speed = 60 / (Travel Time / link distance)

Thus, an urban zone may have a link distance of 1.0 mile yielding a speed of 22.6 miles per hour, while a suburban zone of 1.0 mile has a speed of 41.4 miles per hour. A representative table (Table 3.3) of centroid connector speeds for a distance of one mile would appear as follows:

Table 3.3
Centroid Connector Speeds

Area Type	Distance (miles)	Speed (mph)
CBD	1.0	14.3
Urban	1.0	22.6
Suburban	1.0	24.5
Fringe Suburban	1.0	27.3
Rural	1.0	32.6

Source: H-GAC

3.2.4 HOV Facilities

In 2005, barrier-separated HOV lanes existed in the following freeway corridors; these are:
- Katy Freeway
- Northwest Freeway
- North Freeway
- Eastex Freeway
- Gulf Freeway
- Southwest Freeway

Additionally, non-barrier separated HOV lanes or Diamond lanes existed in these freeway corridors
- Katy Freeway
- Southwest Freeway

Unique links are included in the highway network to represent each of the HOV facilities including ramps and connector links to park-and-rides and transit centers.

3.2.5 Toll Road Facilities

In the 2005 network, toll roads are coded comparably to any freeway link. The actual toll imposed on a vehicle is stored in a user-specified link field and accumulated into a separate toll matrix during the assignment process. Separate toll plaza links are included in the network specifically for this purpose. In the year 2005, there are four toll facilities in the region, which are:

- Hardy Toll Road
- Sam Houston Tollway
- Westpark Tollway
- Fort Bend Tollway

There is an additional network link representing the Houston Ship Channel Bridge which also charges a toll.

3.2.6 Additional Highway Characteristics

Highway terminal time represents the time required to walk from a selected parking space to the ultimate destination of a trip. Historically, terminal time has been determined synthetically by relating the density of employment to the magnitude of the value, that is, the greater the employment density, the higher the value of terminal time. This underlying concept is supported by the fact that as employment density increases, parking supply typically decreases, costs influenced by demand increase, and trip makers begin to "trade-off" walking distance with the availability and price of parking. Currently, terminal times vary from two minutes in residential areas to six minutes in the CBD.

Auto operating costs are an estimate of the out-of-pocket cost paid to operate a private vehicle on a per-mile basis. Cost components included in this variable are based upon fuel cost and fuel economy plus tire, oil, and general maintenance costs. Fixed elements of cost, such as depreciation and insurance costs, are not considered out-of-pocket costs.

3.3 Estimation of Transit Supply Characteristics

A reflection of the level-of-service experienced by a potential transit user is constructed through development of a computerized network representation of the system of routes and service levels. This computer-coded transit network must be an accurate representation of the individual bus routes, fixed guideway lines, headways, and travel times that define that service. Consistency in representation methods across all alternatives is essential to ensure that differences in travel times between those alternatives are accurate portrayals of service level differences, and not simply differences in coding conventions.

Reflection of the choice of "path" or route(s) selected between TAZ's within the network is an equally important consideration in properly determining transit supply characteristics. The algorithm which applies the "path-building" step of the process must examine all the possible ways in which a transit user could travel on one or more transit lines between each pair of

TAZ's. This algorithm selects the path that involves the minimum inconvenience in terms of in-vehicle time, waiting, transferring, and accessing the service.

3.3.1 Transit Routes and Coded Lines

A route in the transit system is typically a set or series of services that operate generally in the same area and over the same streets, but which may offer variations in service origination or termination. The path-building algorithm, however, must be aware of the specific service level options available to each TAZ zone pair, which, therefore, necessitates the representation of each of the variations within a route by means of a separately coded line. Similarly, not all routes or subroutes operate during the course of the entire day. Express and Commuter routes, in particular, generally operate only during the morning and afternoon peak periods. In order to properly reflect these differences, separate peak and base networks are constructed for use in the travel forecasting process.

A trade-off exists between the precision of representation of individual route variations actually operated and the transit service levels perceived by transit users. This tradeoff stems from the manner in which the path-building algorithm measures the frequency of service between boarding and alighting locations. The algorithm recognizes that several lines operating in the same pattern offer a combined frequency of service that is the summation of the frequencies on each individual line. In contrast to other modeling software packages where this recognition occurs only when the lines follow *exactly* the same routing, Cube Voyager allows combined service computation for coded transit network lines that comprise variations in routing or termini.

3.3.2 Headway Calculation

Specification of service frequency for each coded line is an extremely important aspect of the overall network coding process. As outlined above, service is differentiated both by delineation of individual lines (within routes) and also by time period (peak and base). The determination or calculation of a headway value for each line within a time period is related directly to the actual number of bus trips operated.

In the case of the base or off-peak period, the headway is simply the number of hours in the mid-day period divided by the total number of trips provided on that line during mid-day.

Unlike base period service, which tends to be fairly evenly distributed over the entire period, peak service may vary substantially within the peak period. Express lines, for example, may provide relatively few bus trips over the entire period, but may concentrate these trips within a relatively small time interval. Assuming that these trips are appropriately targeted to the specific demand for peak period service, the perceived headway by riders (who will become familiar with the scheduling of the service) will be significantly better than the value implied by using a computation method identical to that for base period service. Therefore, peak headway calculations must be based upon the peak hour of service offered in the peak period, with an appropriate peak hour headway calculated. Table 3.4 summarizes the coded peak and base period headways for each of the lines coded in the transit network.

This approach to coding produces headway values appropriate for the ridership forecasting process, but typically overestimates peak resource requirements: vehicles, vehicle-hours, and vehicle-miles. A separate analysis of resource requirements is conducted in a post-processing environment to resolve this inconsistency.

3.3.3 Transit Travel Times

Travel times are based on: automobile travel times, type of transit service (local, limited, express, etc.), and bus location by sector. The running time of the transit lines over all the network links in each line is calculated using a series of travel time functions (TTF) based on these parameters. Each TTF is referenced with a designated number. Three basic types of TTFs are included in the model:

I. Simple assumed speed

II. Auto speed multiplied by an auto-to-transit time factor

III. Congested speed estimation using BPR function, based on free-flow transit speed compared to minimum transit speed.

Type I TTFs are coded with an assumed speed, which is constant across all links. Type II TTFs apply a multiplicative factor to auto time to relate transit link travel time to the corresponding auto travel time. Type III TTFs estimate congested-speed travel time based on free-flow transit travel time and the v/c ratio of the link. The general form of Type III TTFs is the BPR function, that is:

$$t_c = t_{ff} \times \left(1 + \alpha \times \left(v/c\right)^{4}\right)$$

where t_{ff} is free-flow transit travel time, and α is a multiplicative factor. For all but two TTFs, α is 0.10. For those two TTFs representing nonstop bus operations outside the CBD, α is 0.15. Congested-speed travel time is capped against a maximum time associated with a given minimum transit speed and the resulting time is compared to a minimum time representing auto time on the same link. All three TTFs are used during the peak period, while only Types I and II are used during the off-peak period.

Table 3.5
Peak Transit Travel Time Functions

TTF	Type	Operation	Location	Type I	Type II	Type III	
				Assumed Speed	Auto-to-Transit Time Factor	Free-flow Transit Speed	Minimum Transit Speed

3.3.4 Transit Path Building

Path building between each pair of zones relies upon the coded representation of the transit network as outlined above and a set of "weights" used to value each time component of the trip—walking, waiting, in-vehicle, and transferring. To the greatest extent possible, these weights should be reasonably similar to the "weight" derived from the mode choice model relationships.

The set of path building weights below was the final set of values used in the 1990 validated model (all times are in minutes):

- Boarding time: 1.0
- Boarding time weight (drive access): 1.0
- Boarding time weight (walk access): 10.0
- Waiting time factor: 0.5
- Waiting time weight: 2.0
- Auxiliary transit time weight: 1.5

3.3.5 Transit Modes

In Cube Voyager all network links contain a single letter identifier for each mode allowed to traverse the link. Auxiliary transit modes are defined as walk and auto access modes; these modes represent access to, from, and between transit lines and constitute a portion of a transit trip. The following transit modes were used:

- b: local bus
- c: commuter bus
- x: express bus
- r: rail

The auxiliary transit modes are:

- d: walk access to transit
- e: walk egress to transit
- t: transfer between transit lines
- p: auto access to transit (park-and-ride lots)
- k: auto access to transit (kiss-and-ride lots)
- q: auto access to transit (informal park-and-ride lots)
- w: sidewalk

4.0 Travel Forecasting Procedures

4.1 Introduction

This chapter presents the underlying theory and basis for the structure, formulation, and application of each model component. Also described is the series of steps that were followed to enhance and implement the revised regional mode choice model set, as well as the calibration and validation procedures performed to verify the accuracy and acceptability of the complete model set.

Two key sets of data are input to the model: 1. demographic, socioeconomic and landuse data, and 2. the multimodal transportation network data. In the first stage of the modeling process--trip generation--estimates are developed for fourteen (14) trip purposes:

- Home-based Work person trips (HBW);
- Home-based Nonwork person trips to Retail (HBNW-RET)
- Home-based Nonwork person trips to ED1 (HBNW-ED1)
- Home-based Nonwork person trips to ED1 by School Bus (HBNW-SCHBUS)
- Home-based Nonwork person trips to Airport (HBNW-AIR)
- Home-based Nonwork person trips to Other (HBNW-OTHER)
- Non-home-based person trips – Workbased (NHB-WB);
- Non-home-based person trips – Non-workbased (NHB-NW);
- Taxi vehicle trips (TAXI);
- Truck vehicle trips (TRUCK);
- External-Local Auto trips (EXTL-AUTO);
- External-Local Truck trips (EXTL-AUTO);
- External-Through Auto trips (EXTHR-AUTO);
- External-Through Truck trips (EXTHR-TRUCK).

The Home-based Nonwork person trips to ED1 (HBNW-ED1) trip purpose excludes the person trip by school bus but includes those that use normal transit. The Home-based Nonwork person trips to ED1 by School Bus (HBNW-SCHBUS) is defined as a separate trip purpose in the model set. This was necessary since the mode choice model used in the model set assumes that the person trips by school bus have been removed from the data which is input to the mode choice step. As can be seen in the trip purpose definitions, the non-work person trip purposes are defined around the land use and the attraction end of the trip. Also, non-home-based trips have been separated into those that in which the production is the trip-makers place of employment (work-based) and those in which the production is not the trip makers place of employment (not work-based).

4.2 Trip Generation

Trip generation is performed with a trip production model and a trip attraction model for each trip purpose. These models use the zonal demographic data to estimate the overall magnitude of

trip making, that is, the total number of trip ends (trip productions and trip attractions), for each of the 2,954 detailed traffic analysis zones. Trip estimates by purpose are also prepared for the 46 external stations.

4.2.1 Trip Production

The H-GAC trip household production models use cross-classification trip production rates developed from the H-GAC 1995 Household Travel Survey data. These rates were developed for a two-way cross classification model of household size by household income. Individual cell values in the two way cross classification table were derived by computing the average of the expanded household travel survey for each cell. In the model calibration process, some of the resulting rates are smoothed to remove sampling noise due to the small sample sizes being employed. The resulting production rates (i.e., the dependent variables) are the trips per household by purpose. Cross-classification models allows the nonlinearity of the model with respect to the independent variables. This is a standard practice approach for developing household trip production models.

The trip production model determines the relationship between trips generated per household and household income in combination with household size. Thus, trip production rates are stratified by household income and household size for each trip purpose and are presented in Tables 4.1-4.8.

Due to the high concentration of hotels, motels, and seasonal housing in the Galveston Island area, generation of non-resident trips is also performed. Based on area specific monthly hotel/motel occupancy rates an average rate was applied against the number of units in the Galveston Island area to estimate occupied rooms; this estimate of rooms was multiplied by a NHB trip rate to determine the number of non-resident hotel/motel NHB trips. Likewise, an occupancy rate for seasonal housing factored by a NHB trip rate yielded seasonal housing non-resident NHB trips.

4.2.2 Trip Attraction

Trip attraction rates have been developed based on the 1995 H-GAC workplace survey, the 1995 H-GAC Commercial Vehicle Survey and the 1995 External Station Survey. The attractions rates are stratified by area type and employment category. The rates also include a stratification for households so as to allow for the estimation of trip attractions to households. Additionally, productions for non-home-based work-based trips are estimated based on area type and employment. Table 4.9 through 4.19 present the Cube model trip attraction rates. Attraction rates are not presented for the HBNW-Airport trip purpose as attractions were estimated as part of the special generator trip attraction estimation process.

4.3 Trip Distribution

The trip distribution models are applied at the detailed TAZ level. These models link or connect trip ends estimated in the trip generation model, determining trip interchanges between each pair of zones. In addition to estimates of the magnitude of activity in each TAZ, the models consider the effects of impedance and accessibility on destination choice. The trip distribution models receive direct feedback from trip assignment, a lower model component.

4.3.1 Person Trip Table Development

The Disaggregate Trip Distribution Model, or Atomistic Model, is used for trip distribution modeling in the Houston-Galveston TMA. This model produces twelve (12) trip tables for the HBW, HBNW-ED1, HBNW-ED1-BUS, HBNW-RETAIL, HBNW-AIRPORT, HBNW-OTHER, NHB-Work-Based, NHB-Other, Truck, Taxi, Extl-Auto, Extl-Truck purposes. A modified version of the Atomistic model is used to produce the various external-local vehicle trip tables. Attractions for the external-local trip purposes as well as the origins and destinations for the external-through purposes are based upon patterns derived from 1995 H-GAC External survey and grown to match year 2005 traffic volumes at the external stations. The underlying assumption in the Atomistic model is that trips occur between small parcels of land (atoms) rather than the defined zone structure; thus by dividing existing zones into atoms a more realistic interchange of intrazonal trips and short (less than five minutes) trips among adjacent zones is defined. In application, a gravity model analogy determines the number of trip interchanges between atoms and subsequently sums the trips to derive both intrazonal trips and zonal interchange volumes. The basic atomistic model formulation is:

$$T_{ij} = \frac{\sum_{v=1}^{M_i}\sum_{q=1}^{M_j} p_{iv} a_{jq} F_{dvq} K_{S_{ij}}}{\sum_{x=1}^{N}\sum_{n=1}^{M_j}\sum_{m=1}^{M_x} p_{in} a_{xm} F_{dnm} K_{S_{ix}}} P_i$$

where:

T_{ij} = trips produce in zone I and attracted to zone j

P_{iv} = trips produced by atom v of zone I

P_i = total trips produce in zone I such that:

$$P_i = \sum_{m=1}^{M_i} p_{im}$$

a= relative attraction factor atom q of zone j

A= relative attraction factor for zone j such that:

$$A_j = \sum_{m=1}^{M_j} a_{jm}$$

F= relative trip length factor for estimated separation between atom pair vq

K= bias factor for sector pair containing zones I and j

N= number of zones

My= number of atoms in zone y

In addition to the zonal trip productions and attractions produced in the trip generation process, the trip distribution model requires the zone-to-zone travel times for the estimated minimum time paths on the highway network with 24-hour speeds. The model also requires:

- estimated zonal radii values
- a set of F-factors defining trip length frequency distributions by purpose
- any necessary bias factors (K-factors) by trip purpose

Since the Atomistic Model uses a gravity model analogy that considers travel opportunities within a zone to be spatially distributed rather than concentrated at a single theoretical point (the zone centroid), the spatial dimension of zones is represented by 400 atoms with zonal productions and attractions uniformly distributed among all 400 atoms. The model requires that the distance from the center of a zone to the perimeter be defined in minutes - a zonal radii value. These radii values in conjunction with skimmed travel times determine the spatial distribution of atom pairs for all zonal pairs.

The F-factors used in the 2005 validation were the same set that were developed as part of the 1995 calibration of the Cuba Voyager model set. No changes to F-factors were made as part of the 2005 validation. The calibrated F-factors by purpose are shown in Table 4.21 and 4.22.

K-factors historically have been used to improve model performance in addressing two natural barriers within the Houston-Galveston TMA: the Houston Ship Channel and the separation between Galveston Island and the mainland. These physical barrier K-factors are included in the 1990 model for both work and non-work trip purposes.

Distinct socio-economic and land use characteristics that require introduction of K-factors are the under-representation of both HBW attractions to the Houston CBD and intra-county HBW trips for the surrounding seven counties. In addition to the CBD, three other major activity centers, (Greenway area, Galleria-Post Oak, and Texas Medical Center) also require K-factors. In the 1990 model, the original 1985 model K-factors have been retained except in Brazoria County. Additional K-factors refinements were subsequently made for Brazoria County in conjunction with a county roadway planning effort.

4.4 Unified Mode Choice Model

Mode Choice models are mathematical expressions used to estimate travel market modal shares given various competing mode's time and cost characteristics and the urban resident's demographic and socio-economic characteristics. Mode choice models predict traveler's decisions to choose a particular mode of travel and are designed to be an integral link in the travel demand chain, with *possible* direct feedback mechanisms to a number of related model components -- auto ownership, trip generation, and trip distribution

This part of the report documents the new elements and calibration process of the Unified Mode Choice Model. This work effort is part of a larger effort to transition Houston METRO's transit modeling system, originally residing in EMME/2, to Cube-Voyager's Public Transportation module (PT). Only the changes to Unified Mode Choice Model and related elements will be described in this document. For further details, the reader should consult the *Description of Houston METRO's Travel Demand Models: Technical Report* issued in November 2006.

Summary of Revisions

The transit model was revised to be consistent with known FTA New Starts modeling guidance. Although the model is able to produce files used in user benefit analyses (via Summit), it would not be acceptable to use it for New Starts analysis at this time. Other items that would need to be addressed before beginning a New Starts analysis are: a detailed examination of person trips at a district-to-district level by purpose, socio-economic class, mode and geography; analysis of point-to-point travel times by mode between major activity areas; and informing the model of current transit travel patterns using the 2007 on-board survey.

The following sections describe the changes in greater detail. These revisions were made to the transit model:

- Modifications to walk-access, drive-access and transfer connector criteria,
- The wait curves were modified to better reflect the bifurcated wait time,
- Transit fares were coded in 2007$ and adjusted to 1985$ in the mode choice model,
- Revisions to the weights of the travel components,
- Revised mode choice structure to be more flexible for future analyses,
- Simplified the mode choice sub-modal utilities,
- Minor changes to the utility coefficients, and
- Addition of a transit assignment reporting routine.

Access Connectors

Walk-Access
The original walk connector logic added connector links to the highway network based on stops and their distance to centroids. This logic was replaced with PT's native process for simplicity and better consistency with the percent walk data.

Walk-access connectors have a maximum walking distance of 0.15 miles (3 minutes of walking time). This corresponds with the percent walk data, which lists the zonal coverage area using quarter-mile buffers. Initial tests showed that many large zones were disconnected since their centroid connectors exceeded the maximum walking distance. The preferred method of addressing this issue is to subdivide the zones. Since this was not possible in the given timeframe and budget – and H-GAC will shortly undertake such an effort – the distance of all centroid connectors was adjusted to 0.15 miles if the original distance exceeded that value.

The maximum length of walk-access connectors in the Central Business District (CBD) were extended to 0.60 miles to reflect the good walk access available and avoid artificial transfers that typically occur because of high frequency of buses downtown.

A special set of walk-access connectors to rail stations is developed to reflect their higher attractiveness and accessibility. The maximum walk distance is set to three miles. The distance has been kept artificially high to avoid unintentional disconnections in New Starts Analysis. All rail stations in the model are identified by nodes on FTYPE 130s links.

Auto-Access
Auto-access connectors are built only for PNRs. The criteria were modified slightly to improve consistency in connectors to the five modes. The pseudo-PNR logic in the original model has been discontinued.

Transfer
The somewhat restrictive transfer connector logic in the original model has been revised slightly. Transfer connectors can now use more than two highway links and the number of connectors is not limited by the length of the shortest connector.

Transit Network

Transit fares have been coded in 2007$ to make future changes easier. The fares are deflated to 1985$ using the TransitFareInflationFactor catalog key. This value is currently set to 0.551. In addition, operator codes were added to each route to assist in calculating different fare structures.

The coding of several rail stations was shifted to better coincide with their actual location. Rail station-to-station travel times have been hard-coded and checked against known operating speeds. The time for each station-to-station link is maintained in a file named LRTLINKS.PRN, which resides in the input folder. The format of the file is shown in the following table.

LRTLINKS.PRN File Format

Columns	Format	Description
1-6	I6	Anode
7-12	I6	Bnode
13-20	F8.2	Station-to-station travel time in min (includes dwell time)
21-100	A80	Description

Some transit routes were modified to connect them to centroid connectors. Public timetables were consulted to make sure that the original non-stops were not intentionally coded.

Wait Curves

The wait curves were modified to accurately reflect the bifurcated wait time mode choice coefficients. This improves consistency between the path-builder and mode choice model. Separate wait curves were developed for HBW and HBNW/NHB paths.

The wait curves reflected perceived (i.e., weighted) wait time. Consequently, the mode choice coefficients are set to 1.0x in-vehicle travel time.

HBW Wait Curves

Initial Wait Curve			Transfer Wait Curve		
	Wait Time			Wait Time	
Freq	Unweighted	Weighted	Freq	Unweighted	Weighted
0	-	-	0	-	-
1	0.50	1.00	1	0.50	1.29
4.5	2.25	4.50	4.5	2.25	5.81
5	2.50	5.00	5	2.50	6.45
9	4.50	9.00	9	4.50	11.61

60	30.00	60.00	60	30.00	60.00
70	35.00	70.00	70	35.00	70.00
120	60.00	120.00	120	60.00	120.00
180	60.00	120.00	180	60.00	120.00

Transit Paths

Transit paths have been revised to reflect the new mode choice structure. Four paths are built for HBW with a similar four paths built for the HBNW/NHB trip purposes:

- Walk-to-local bus only,
- Walk-to-mixed mode,
- Drive-to-local bus only, and
- Drive-to-mixed mode.

The HBW paths use the peak period, while the HBNW/NHB paths are built using off-peak period service. The “local bus only” paths allow the use of local buses and prohibit all other modes. All modes are available in the “mixed mode” paths, although local buses are slightly disfavored.

The weights of the travel time components have been modified to be more consistent with the same mode choice variables. The revised path weights are listed in the tables below.

HBW Path Weights

Transit	Walk-Access		PNR-Access		KNR-Access	
	LBO	MM	LBO	MM	LBO	MM
Boarding Penalty (all modes)	10.00	10.00	10.00	10.00	10.00	10.00
Transfer Penalty (all modes to all modes)	4.00	4.00	4.00	4.00	4.00	4.00
1st Wait time *	1.00	1.00	1.00	1.00	1.00	1.00
Transfer wait time *	1.00	1.00	1.00	1.00	1.00	1.00
Runtime Factors

Commuter Bus	-	1.00	-	1.00	-	1.00
Light Rail	-	1.00	-	1.00	-	1.00
Commuter Rail	-	0.80	-	0.80	-	0.80

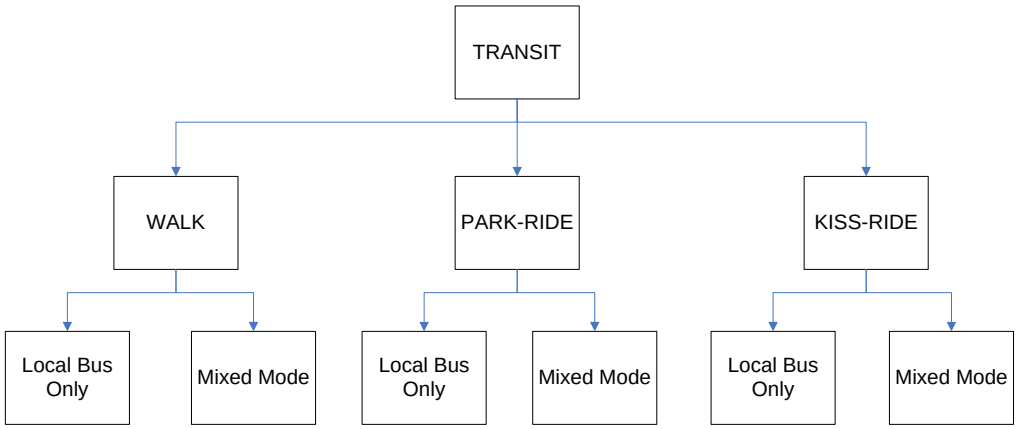
Due to its design, PT will always find a transit path on an interchange, even when walking between zones would be shorter and more direct. To address this issue, an extra walk-only path is built between all zones within seven miles of each other. The results of these “all-walk” paths are compared to each transit path. If the “all-walk” path skim is less onerous, the transit path is zeroed out before sent to the mode choice model for processing.

Mode Choice Model

The structure of the mode choice model is the biggest change to the original H-GAC travel demand model. The previous model structure was based on a modal. While this structure was helpful in past analyses, it did present some forecasting issues. First, it does not reflect the fact that express and commuter bus services do not directly compete in most instances. Also, there was some concern that the hierarchy would continue in the future, especially with planned services and modes. Assigning a new mode a place in the hierarchy has large behavioral and user benefit impacts as strong assertions are made how the mode is used in conjunction with other modes and how future travelers would view the importance of that mode in selected their paths.

The new structure is now much simpler and has several key advantages. It dispenses with the need to assign a new mode’s relationship to other modes. Also, it allows the non-local bus modes (i.e., express bus, commuter bus and METRORail) to freely interact without any *a priori* path restrictions. Most importantly, it reflects the current path trade-off between local bus and all other modes.

New Mode Choice Structure



The transit utilities have been streamlined for clarity and consistency in a number of ways:

- All constants are input at the top-level for easy interpretation,
- The numerous sub-modal penalties and bonuses (e.g., a distance bonus for using commuter bus) that do not have a direct relationship to the modal attributes have been removed,
- Auto operating cost has been added to the KNR utility,
- The PNR and KNR utilities now use drive-access distance rather than drive-alone distance for their auto operating cost calculation,
- Commuter rail in-vehicle time has a coefficient that have a value of 0.8 minutes of regular transit in-vehicle time,
- Inflation factors have been added so that fares, parking costs, tolls and auto operating costs can be input in base year dollars, and
- The lowest income groups are prohibited from park-riding.

The variable mapping to the sub-modal utilities as well as the nesting coefficients are shown in Tables 4 and 5 for HBW, Tables 7 and 8 for HBNW, and Tables 10 and 11 for NHB. The final constants are shown in Tables 6, 9 and 12.

There are five constants that can be applied to the mixed-mode utility, one for each sub-mode. The constant of the sub-mode that has the most in-vehicle travel time is applied to the utility. For example, a mixed-mode path with 35 minutes of commuter bus, 10 minutes of rail and 5 minutes of local bus time will have the commuter bus bias constant applied. A similar path with 10 minutes of rail and 40 minutes of local bus will have the local/mixed mode constant applied. Please note that a mixed-mode path with only local-bus is conditioned out of the skim before mode choice.

Transit Assignment

Transit trips are loaded unto the transit network using PT's transit assignment procedures. At this time, PT does not have a satisfactory reporting mechanism, so an external program named TAREPORT was developed.

The program produces two summary files, one summary report at the route level (TASUM_Axx.PRN, where xx is the alternative year) and another report that provides stop-level detail for each route (TAROUTE_Axx.PRN). Information in both reports is shown for the peak, off-peak and daily time periods. In addition, the summary report provides totals by mode and operator.

Calibration and Validation

Houston METRO has conducted two transit on-board surveys in the past five years. The latest transit on-board survey available was conducted in 2002 and does not reflect the METRORail system (which began operations in 2004) or the system-wide changes to bus operations implemented around the same time. METRO recently completed an on-board survey in spring 2007. A summary report is available from that survey, but detailed data records are not yet available. Therefore, this 2005 calibration and validation process is based on merging all available information: both on-board surveys as well as 2005 boarding information and detailed linked trip targets from METRO's 2005 calibration of its travel demand model. The primary goal of calibration was not to match linked trip targets *per se*, but achieve the 2005 observed boardings in assignment since that data is most reflective of 2005 transit travel patterns.

Initial linked trip targets were developed by dividing the 2005 boardings (detailed by mode) by transfer rates listed in the 2007 on-board survey summary report. The resulting aggregate linked trips were disaggregated by purpose, income group, access and sub-mode by applying the same breakdown (by percentage) from METRO's 2005 linked trip targets. The structure of the two mode choice models is quite different as noted in the previous section, so some modifications were made to achieve the 2005 boardings shown in the following table. Almost all of the adjustments involved "trading" trips between access modes and sub-modes.

During calibration, the targets for walk-commuter bus trips for income groups 1-3 were removed because the very small amount of trips (less than 500 trips combined for the three income groups) made it very difficult to calibrate given the information we have. It is hoped that the better data contained in the 2007 on-board survey will provide more insights. A comparison of observed and estimated boardings is shown in the following table.

2005 Observed & Estimated Boardings

Mode	Observed	Estimated	Relative Difference
Local Bus	226,786	226,606	0%
Express Bus	17,711	19,344	9%
Commuter Bus	30,902	32,439	5%
METRORail	33,706	33,802	0%
Total	309,105	312,191	1%

Tables 4.24, 4.25, and 4.26 show the observed and estimated linked trips for the HBW, HBNW and NHB trip purposes, respectively. The final constants are shown in Tables 4.28, 4.30 and 4.32. Final calibration results are shown in the following table.

2005 H-GAC Calibration – TRAVEL MODEL RESULTS

	Category	Description	Result
BOX 1	Trip Data	**Total person trips in the system**	
		Home-based work trips	3,414,112
		Home-based nonwork trips	8,551,781
		Non-home based trips	5,241,184
		Total trips	**17,207,077**
BOX 2	Demographic Data	Total population	5,214,051
		Total households	1,865,189
		Trips per household	9.23
		Total employment	2,525,285
BOX 3	Transit Trips	**Linked transit trips in the system**	**204,959**
		Total Walk trips	161,815
		Total PNR trips	37,975
		Total KNR trips	5,169
		Daily boardings (unlinked trips)	**312,191**
		Local bus	226,606
		Express bus	19,344
		Commuter bus	32,439
		LRT	33,802
BOX 4	Auto Person Trips	**Auto trips**	
		Single Occupants	9,691,359

		Daily transit mode share to CBD	18.3%
		Work trips only	
		Total daily trips (auto+transit) to CBD	134,907
		Total daily transit trips to CBD	50,101
		Daily transit mode share to CBD	37.1%
BOX 6	VMT & VHT Data	**VMT and VHT Data**	
		VMT - Transit System	
		VHT - Transit System	
		Passenger miles - Transit system	2,505,386
		Passenger hours - Transit system	160,548
		8-county region	
		VMT - Highway system	140,379,076
		VHT - Highway system	3,617,936

After calibration/validation, a user benefit test was conducted to confirm whether the procedures that produce the user benefit data files (to be used by Summit) worked correctly. A dummy rail line was coded for the build alternative and a bus that exactly mimicked the rail line as the baseline alternative. The rail line is about three minutes faster (end-to-end) than the baseline bus.

4.5 Commercial Vehicles

In the Cube models, commercial vehicle trips include truck and taxi trips. Trips for each of these purposes are separately estimated. Truck and taxi vehicle trips were estimated based on trip attraction rates developed from the 1995 H-GAC Commercial Vehicle survey and trip productions are scaled to match trip attractions. These trips are maintained as a separate class of trip in the auto assignment. Highway travel times represent the purpose impedance.

4.6 External Travel

External trips are categorized into two general categories: external local (external-internal travel) and external through (external-external travel). Within these categories, truck and auto trips have been separated, resulting in four different trip purposes: external-local auto, external-local truck, external-through auto and external-through truck. External-local auto and truck productions are estimated based on the year 2002 counted volumes at the external station and the shares of external-local auto and truck as estimated from the H-GAC 1995 External-station survey. External-local attractions are estimated based upon the household survey. External-local attractions are scaled to match external-local productions.

The trip distribution model employs the gravity model form in conjunction with a specified trip length frequency curve. External through trip matrices are derived by frataring the 1995 External Survey based external-through trip tables to match estimated year 2002 external-through trip ends. The year 2002 estimated external through trip ends are based upon the external-through trip share as estimated at each station based upon the 1995 External Survey.

4.7 Trip Assignment

4.7.1 Highway Trip Assignment Methodology

Using the mode choice model, person trips classified by trip purpose are separated into automobile and transit trips and auto person trips are converted to vehicle trips based on vehicle occupancy factors. These vehicle trip tables are summed and converted to origin-destination format and assigned to the appropriate highway network (base year or forecast year). This is a 24-hour capacity restraint assignment performed at the TAZ level. Multiple iterations of the capacity restraint model precede computation of the final assignment results. The model adjusts link impedance between iterations, based on each link's assigned V/C ratio. The weighted average of the assigned volumes from the preceding iterations is used to calculate the V/C ratio. The impedance adjustment function used in this model is based on the FHWA impedance adjustment function. This function assumes impedance is based on a "zero-volume" link speed. However, since traditional coding of Texas highway networks used a 24-hour speed rather than a zero-volume speed, a modified version of the FHWA impedance adjustment function was developed, which is represented by the following formula:

$$I_{n+1} = \left(0.92 + 0.15\left(V/C\right)^4\right) \times I_0$$

Where: I_0 = initial impedance using 24-hour input speed
I_{n+1} = link impedance for iteration n + 1
v = weighted average link volume from iterations 1 to n
c = link capacity

The constraint is applied to limit the magnitude of the impedance adjustment, the maximum of which varies by iteration. After the initial assignment, the maximum impedance factor is two (essentially reducing the 24-hour speed by one-half) and is increased by one for each of the subsequent iterations. The final assignment results are computed following the six iterations, using a weighted average of the link volumes from those iterations. The iteration weights specified for the 1990 base year assignment are determined by an equilibrium capacity restraint process, where each trip is assigned the path with the shortest travel time until equilibrium is achieved.

4.7.2 Comparison to 2005 Counted Volumes

In the 2005 network, there are 28,888 highway links (one-way links) excluding centroid connectors. Of the 28,888, there are 6,165 with count based volume estimates. To demonstrate the validity of the models, comparison of the assigned versus counted VMT is normally summarized to demonstrate the capabilities of the models in matching estimated 2005 base year conditions.

Table 4.36 summarizes the total assigned VMT on all 28,888 links by 5 roadway types. The assigned VMT on the 6,165 links with counted volumes are also summarized by roadway type. The assigned VMT as a percentage of the counted VMT was computed and is summarized for each of the roadway types. As may be observed, the assigned VMT on freeways, principal arterials, Tollways and minor arterials are within 5% of the counted VMT estimates

Table 4.37 summarizes the total assigned VMT on all 28,888 links by 5 area types. The assigned VMT on the 6,165 links with counted volumes are also summarized by area type. The assigned VMT as a percentage of the counted VMT was computed and is summarized for each of the area types. While the CBD Assigned VMT is approximately 88.3% of counted VMT, this is not unusual for CBD's and is considered within acceptable limits. The assigned and counted VMT in the other area types compare very favorably.

Table 4.38 summarizes the total assigned VMT on all 28,888 links by the 8 counties in the region. The assigned VMT on the 6,165 links with counted volumes are also summarized by county. The assigned VMT as a percentage of the counted VMT was computed and is summarized for each of the counties.

Overall the comparisons of the assigned and counted VMT were considered acceptable and reasonably demonstrate that the models reasonably replace the observed conditions for 2005.

Table 4.36
2005 VMT by Roadway Type

Roadway Type	Number of links	Total Assigned VMT (all links)	Number of Links With Counts	Assigned VMT on Links With Counts	Count VMT	Assigned VMT as Percent of Counted VMT
Freeway	3,066	51,392,093	372	9,310,753	9,576,413	97.2%

5.0 HPMS VMT ADJUSTMENT

5.1 INTRODUCTION

H-GAC has validated its travel models to the year 2005. As part of the validation, there is a need to re-calculate the factor by which travel model VMT is made to be consistent with VMT estimated by the FHWA Highway Performance Monitoring System (HPMS). The H-GAC Regional Travel Models have been validated to observed vehicle miles of travel (VMT) that are estimated based on roughly 14,000 traffic counts. The estimates and forecasts of vehicle miles of travel produced by the model set are used directly in all transportation planning applications conducted by H-GAC and its transportation planning partners. For purposes of air quality conformity analysis of RTPs and TIPs and the development of State Implementations Plans, H-GAC, through consultation with the Texas Department of Transportation (TxDOT), Texas Commission on Environmental Quality (TCEQ), U.S. DOT and EPA has chosen to reconcile its Base Year (2005) model estimated regional VMT against regional 2005 VMT estimated by HPMS. The factor needed to reconcile model estimated VMT to HPMS estimated VMT is used for all air quality conformity analysis and development of SIPs.

5.2 COMPARISON OF ESTIMATED VMT

In order to compare Base Year 2005 estimated regional VMT to HPMS estimated 2005 VMT, an estimate of total model estimated regional VMT is calculated. Model assigned regional network VMT is combined with assigned regional centroid connector VMT and an estimate of travel within each zone (intrazonal VMT). Because the reconciliation is made for estimated non-summer weekday VMT, both VMT estimates (model and HPMS) are made to represent non-summer weekday VMT. The model VMT is produced in its original form as non-summer weekday VMT, as shown. HPMS VMT represents average annual daily travel (AADT) and is adjusted to represent average non-summer weekday travel, based on an adjusted factor developed using TxDOT permanent traffic recorder data.

Model estimated average non-summer weekday travel (ANSWT)
= (Model network VMT) + (Model Centroid Connector VMT) + (Model Intrazonal VMT)
= (126,139,292) + (12,627,263) + (856,596)
= 139,623,151

HPMS estimated average non-summer weekday travel (ANSWT)
= (HPMS AADT) * (AADT to Non-Summer Weekday Travel Adjustment Factor[A])
= (132,093,142) * (1.059088)
= 139,898,262

A – 2006 HGB ATA Data

5.3 CALCULATION OF HPMS ADJUSTMENT FACTOR

The factor used to reconcile model estimated regional VMT to HPMS estimated regional VMT is calculated by dividing the HPMS estimated average non-summer weekday VMT as follows:

HPMS Adjustment Factor

= (HPMS estimated ANSWT) / (Model estimated ANSWT)
= (139,898,262) / (139,623,151)
= 1.001970381

5.4 APPLICATION OF HPMS ADJUSTMENT FACTOR

The HPMS adjustment factor is applied to the model estimated time-of-day VMT prior to the estimation of time-of-day speed. In this way, the time-of-day speeds used in the estimation of emissions are based upon HPMS adjusted VMT.
